Chapter 6 Deadlocks

Preemptable and Nonpreemptable Resources

Sequence of events required to use a resource:

- 1. Request the resource.
- 2. Use the resource.
- 3. Release the resource.

Resource Acquisition (1)

```
typedef int semaphore;
                                            typedef int semaphore;
semaphore resource_1;
                                            semaphore resource_1;
                                            semaphore resource_2;
void process_A(void) {
                                            void process_A(void) {
     down(&resource_1);
                                                 down(&resource_1);
                                                 down(&resource_2);
     use_resource_1();
     up(&resource_1);
                                                 use_both_resources();
                                                 up(&resource_2);
                                                 up(&resource_1);
             (a)
                                                         (b)
```

Figure 6-1. Using a semaphore to protect resources. (a) One resource. (b) Two resources.

Resource Acquisition (2)

Figure 6-2. (a)
Deadlock-free code.

```
typedef int semaphore;
     semaphore resource_1;
     semaphore resource_2;
     void process_A(void) {
          down(&resource_1);
          down(&resource_2);
          use_both_resources();
          up(&resource_2);
          up(&resource_1);
     void process_B(void) {
         down(&resource_1);
          down(&resource_2);
          use_both_resources();
          up(&resource_2);
         up(&resource_1);
             (a)
```

Resource Acquisition (3)

Figure 6-2. (b) Code with a potential deadlock.

```
semaphore resource_1;
semaphore resource_2;
void process_A(void) {
    down(&resource_1);
    down(&resource_2);
    use_both_resources();
    up(&resource_2);
    up(&resource_1);
void process_B(void) {
    down(&resource_2);
    down(&resource_1);
    use_both_resources();
    up(&resource_1);
    up(&resource_2);
```

Introduction To Deadlocks

Deadlock can be defined formally as follows:

A set of processes is deadlocked if each process in the set is waiting for an event that only another process in the set can cause.

Conditions for Resource Deadlocks

- 1. Mutual exclusion condition
- 2. Hold and wait condition.
- No preemption condition.
- 4. Circular wait condition.

Deadlock Modeling (1)

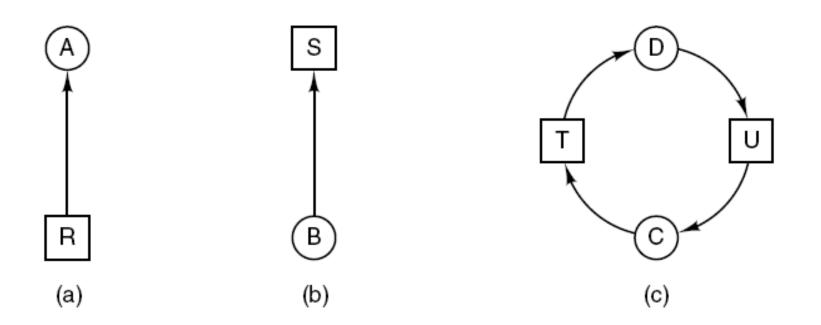

Figure 6-3. Resource allocation graphs. (a) Holding a resource. (b) Requesting a resource. (c) Deadlock.

Deadlock Modeling (2)

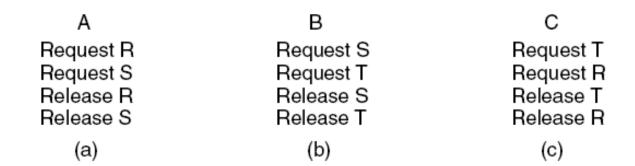

Figure 6-4. An example of how deadlock occurs and how it can be avoided.

Deadlock Modeling (3)

Deadlock Modeling (5)

Strategies for dealing with deadlocks:

- 1. Just ignore the problem.
- 2. Detection and recovery. Let deadlocks occur, detect them, take action.
- 3. Dynamic avoidance by careful resource allocation.
- 4. Prevention, by structurally negating one of the four required conditions.

Deadlock Detection with Multiple Resources of Each Type (1)

Resources in existence
$$(E_1, E_2, E_3, ..., E_m)$$

Current allocation matrix

Row n is current allocation to process n

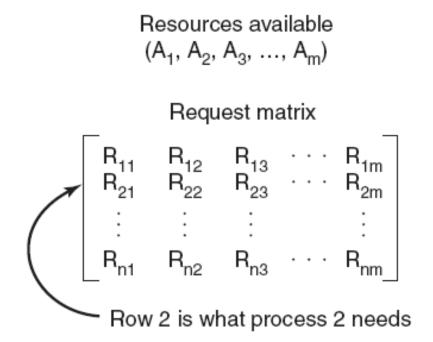

Figure 6-6. The four data structures needed by the deadlock detection algorithm.

Deadlock Detection with Multiple Resources of Each Type (2)

Deadlock detection algorithm:

- 1. Look for an unmarked process, P_i , for which the i-th row of R is less than or equal to A.
- 2. If such a process is found, add the *i-th* row of *C* to *A*, mark the process, and go back to step 1.
- If no such process exists, the algorithm terminates.

Deadlock Detection with Multiple Resources of Each Type (3)

Tape drives
$$A = (4 \ 2 \ 3 \ 1)$$

$$A = (2 \ 1 \ 0 \ 0)$$

Current allocation matrix

$$C = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 2 & 0 & 0 & 1 \\ 0 & 1 & 2 & 0 \end{bmatrix}$$

Request matrix

$$R = \begin{bmatrix} 2 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \\ 2 & 1 & 0 & 0 \end{bmatrix}$$

Figure 6-7. An example for the deadlock detection algorithm.

Recovery from Deadlock

- Recovery through preemption
- Recovery through rollback
- Recovery through killing processes

Safe and Unsafe States (1)

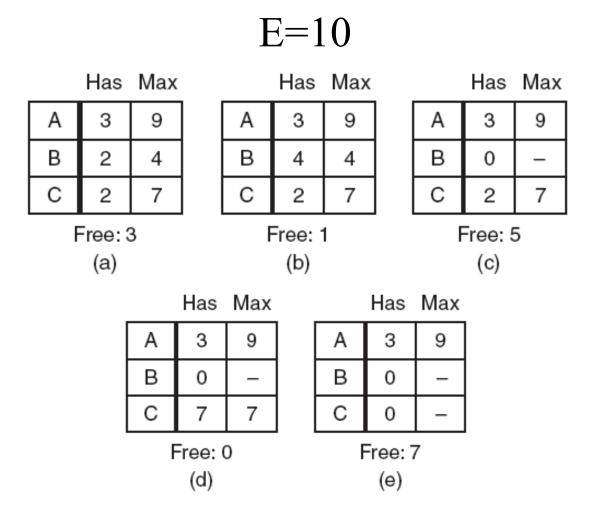

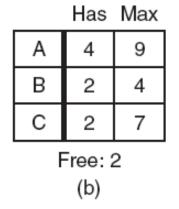

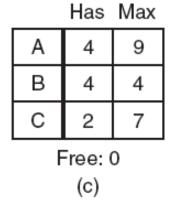

Figure 6-9. Demonstration that the state in (a) is safe.

Safe and Unsafe States (2)

E = 10

	Has	Max		
Α	3	9		
В	2	4		
С	2	7

(c)

Figure 6-11. Three resource allocation states: (a) Safe. (b) Safe. (c) Unsafe.

The Banker's Algorithm for Multiple Resources (1)

Algorithm for checking to see if a state is safe:

- Look for row, R, whose unmet resource needs all ≤ A. If no such row exists, system will eventually deadlock since no process can run to completion
- 2. Assume process of row chosen requests all resources it needs and finishes. Mark process as terminated, add all its resources to the A vector.
- 3. Repeat steps 1 and 2 until either all processes marked terminated (initial state was safe) or no process left whose resource needs can be met (there is a deadlock).

The Banker's Algorithm for Multiple Resources (2)

Figure 6-12. The banker's algorithm with multiple resources.

Deadlock Prevention

- Attacking the mutual exclusion condition
- Attacking the hold and wait condition
- Attacking the no preemption condition
- Attacking the circular wait condition

Other Issues

- Two-phase locking
- Communication deadlocks
- Livelock
- Starvation
